1 Introduction

The total energy of the system is given as

$$E_{tot} = E_{kin} + E_{rot} + E_{vib} \quad (1.1)$$

the individual components can be expressed as assuming a common kinetic temperature of the mixture

$$E_{kin} = \frac{3}{2} k_B T \sum_i N_i \quad (1.2)$$

$$E_{rot} = k_B \sum_i^{N_s} N_i \frac{\xi_i}{2} T_i \quad (1.3)$$

$$E_{vib} = k_B \sum_i^{N_s} \left(N_i \sum_m g_{i,m} \frac{\theta_{i,m}}{\exp(\theta_{i,m}/T_{i,m}) - 1} \right) \quad (1.4)$$

where the index i denotes the species and m the vibrational mode. We assume a constant volume thus we can work with per volume quantities and replace the particle number N with number density n . Assuming a thermalized rotational temperature we can write the per particle energy as

$$e_{kr,i} = \frac{3 + \xi_i}{2} k_B T \quad (1.5)$$

$$e_{v,i,m} = k_B g_{m,i} \frac{\theta_{i,m}}{\exp(\theta_{i,m}/T_{i,m}) - 1} \quad (1.6)$$

and therefore

$$\underbrace{E_{kin} + E_{rot}}_{E_{kr}} = \sum_i n_i e_{kr,i} = T k_B \sum_i n_i \frac{3 + \xi_i}{2} \quad (1.7)$$

$$E_{vib} = \sum_i \left(n_i \sum_m e_{v,i,m} \right) \quad (1.8)$$

We have

$$\frac{\partial E_{kr}}{\partial t} = \sum_i \left(\frac{\partial n_i}{\partial t} e_{kr,i} + n_i \frac{\partial e_{kr,i}}{\partial t} \right) + \Delta E_R \quad (1.9)$$

$$\frac{\partial E_{vib}}{\partial t} = \sum_i \sum_m \left(\frac{\partial n_i}{\partial t} e_{v,i,m} + n_i \frac{\partial e_{v,i,m}}{\partial t} \right) \quad (1.10)$$

$$\Delta E_R = \sum_r \nu_r \Delta e_r \quad (1.11)$$

$$\frac{\partial n_i}{\partial t} = \sum_k n_i n_k r_{i,k}(T) \quad (1.12)$$

$$\frac{\partial e_{kr,i}}{\partial t} = - \sum_m \frac{\partial e_{v,i,m}}{\partial t} \quad (1.13)$$

$$\frac{\partial e_{v,i,m}}{\partial t} = \frac{e_{v,i,m}(T) - e_{v,i,m}(T_{i,m})}{\tau_{i,m}} \quad (1.14)$$

2 Fundamentals

Given a closed system of constant volume the total energy of the system E is given as

$$E = \sum_{s=1}^{N_s} e_s n_s \quad (2.1)$$

where e_s is the energy of a particle of species s and n_s is the number density of said species. The total energy has the unit $[E] = \text{J m}^{-3}$. The energy of a species consists of the kinetic energy e_k , the rotational energy e_r and the vibrational energy e_v . It is assumed that the translational energy is in equilibrium between the individual species $e_{t,s} = e_t$ therefore we get

$$E = e_t \sum_{s=1}^{N_s} n_s + \sum_{s=1}^{N_s} (e_{r,s} + e_{v,s}) n_s. \quad (2.2)$$

For polyatomic species the vibrational energy is the sum of vibrational energies of individual modes m

$$E = e_t \sum_{s=1}^{N_s} n_s + \sum_{s=1}^{N_s} \underbrace{\left(e_{r,s} + \sum_{m=1}^{N_m} e_{v,s,m} \right)}_{e_{int,s}} n_s. \quad (2.3)$$

Assuming chemical reactions the change of energy is

$$\frac{\partial E}{\partial t} = \dot{r} \quad (2.4)$$

where $\dot{r}$ is the energy change due to chemical reactions

$$\dot{r} = \sum_{r=1}^{N_r} \nu_r \Delta e_r \quad (2.5)$$

where ν_r is the rate of reaction r and Δe_r is the energy release of said reaction. The reaction rate is give as $[\nu_r] = \text{reactions}^{-1} \text{m}^{-3}$ and $[\Delta e_r] = \text{J}$. The total change of the energy in time is

$$\frac{\partial E}{\partial t} = \frac{\partial e_t}{\partial t} \sum_{s=1}^{N_s} n_s + e_t \sum_{s=1}^{N_s} \frac{\partial n_s}{\partial t} + \sum_{s=1}^{N_s} \frac{\partial e_{int,s}}{\partial t} n_s + \sum_{s=1}^{N_s} e_{int,m} \frac{\partial n_s}{\partial t} \quad (2.6)$$

$$= \frac{\partial e_t}{\partial t} \sum_{s=1}^{N_s} n_s + \sum_{s=1}^{N_s} \frac{\partial e_{int,s}}{\partial t} n_s + \sum_{s=1}^{N_s} e_s \frac{\partial n_s}{\partial t}. \quad (2.7)$$

The change of number density in time is given as

$$\frac{\partial n_s}{\partial t} = \sum_{r=1}^{N_r} \nu_r \alpha_{r,s} \quad (2.8)$$

where $\alpha_{r,s}$ is the stoichiometric coefficient of species s in reaction r .

The change of an internal energy mode being it rotational or vibrational is given as

$$\frac{\partial e_m}{\partial t} = \frac{e_m(T) - e_m}{\tau_m} \quad (2.9)$$

where τ_m is the relaxation time of mode m and T is the translational temperature given as

$$e_t = \frac{3}{2} k_B T \quad (2.10)$$

i.e.

$$T = \frac{2}{3} \frac{e_t}{k_B}. \quad (2.11)$$

The change of translational energy is therefore given as

$$\frac{\partial e_t}{\partial t} = - \frac{\sum_{s=1}^{N_s} \partial_t e_{int,s} n_s + \sum_{s=1}^{N_s} e_s \partial_t n_s}{\sum_{s=1}^{N_s} n_s} \quad (2.12)$$

Using $n_{tot} = \sum_{s=1}^{N_s} n_s$ we can write

$$\frac{\partial e_t}{\partial t} = - \frac{1}{n_{tot}} \sum_{s=1}^{N_s} \left(\frac{\partial e_{int,s}}{\partial t} n_s + e_s \frac{\partial n_s}{\partial t} \right). \quad (2.13)$$

2.1 $T_t = T_r$

Assuming $T_t = T_r$ we have

$$e_{tr} = T k_b \left(\frac{3}{2} + \sum_s \frac{\xi_s}{2} \right) \quad (2.14)$$

where ξ_s is the number of rotational degrees of freedom of species s . Therefore we have

$$T = \frac{2}{3 + \xi_r} \frac{e_{tr}}{k_B} \quad (2.15)$$
